

Club Registration System

A web-based application for registering college-club members and managing the member directory.

Student detail	Information
Student name	Ali Sahban
Roll number	MLU24F035
Division	A
Project title	Club Registration System

Hosted application:

<http://clubmember.rf.gd/index.php?success=1>

Prepared from the PHP, CSS, and configuration files supplied for this project. The actual SQL export and browser screenshots were not included; database types and test outputs are therefore identified as proposed/expected where applicable.

1. Problem Statement, Objective & Features

Selected problem statement: Register college-club members with name, branch, club, and interest area; view membership list.

Objective: To provide a simple web application that collects club-member information, stores it in a MySQL database, and lets users browse, search, inspect, update, or delete membership records.

The application uses a browser-based form and PHP server-side scripts. Its home page presents a registration form and a member directory.

Main features found in the supplied code

Feature	Description
Registration form	Collects full name, branch/department, club, and area of interest. All fields are required; client-side maximum lengths are
Insert and confirmation	save.php validates submitted values, inserts a row using a prepared statement, then redirects to a success message.
Member directory	index.php lists members newest-first, displays a count, and provides a View / edit link.
Search	search.php searches name, branch, club, or interest using a keyword and displays matching records.
View / edit	view.php fetches one record by ID and allows its fields to be updated.
Delete	view.php provides a delete action with a browser confirmation prompt.
Responsive styling	style.css defines a clean blue/white layout and adjusts the form for narrow screens.

Technology stack

Technology	Role in this project
HTML	Page structure, form controls, links, and tables.
CSS	Layout, colors, typography, responsive presentation.
PHP	Request handling, validation, database queries, redirects, and output rendering.
MySQL / MySQLi	Stores and retrieves club-member records.
InfinityFree	Hosting platform for the deployed PHP application.

2. Database Design & ER / Table Schema

The PHP files consistently refer to a table named **club_members** in the database configured as **if0_42736450_clubdb**. The supplied files do not include a CREATE TABLE statement or a phpMyAdmin schema screenshot. The following column types are a **proposed schema inferred from the code**; confirm them against the live database before submission.

Column	Suggested MySQL type	Key / constraint	Purpose
member_id	INT UNSIGNED	PRIMARY KEY, AUTO_INCREMENT	Unique member identifier
member_name	VARCHAR(80)	NOT NULL	Member's full name
branch	VARCHAR(50)	NOT NULL	Branch / department
club	VARCHAR(60)	NOT NULL	Selected club
interest_area	VARCHAR(80)	NOT NULL	Member's interest
created_at	TIMESTAMP	DEFAULT CURRENT_TIMESTAMP	Registration timestamp

The form's client-side club options include Technical, Cultural, Photography, Sports, Literary, and Other. The server code checks that each field is non-empty and enforces maximum lengths before inserting.

club_members
PK member_id : INT
member_name : VARCHAR(80)
branch : VARCHAR(50)
club : VARCHAR(60)
interest_area : VARCHAR(80)
created_at : TIMESTAMP

One table; each row represents one registered member.

ER interpretation: This implementation uses one entity/table, so no relationship between multiple tables is evidenced in the supplied files.

3. Application Flow & SQL Operations

Application flow

The home page executes a SELECT to show all members ordered by descending member ID. Search uses a GET keyword and returns matching rows. Selecting a member opens `view.php?id=...`; this page loads the record and accepts update or delete POST actions.

SQL operations present in code

Operation	Where / purpose
INSERT	save.php inserts member_name, branch, club, and interest_area.
SELECT (list)	index.php selects member fields and created_at, ordered by member_id DESC.
SELECT (search)	search.php uses LIKE against name, branch, club, and interest area.
SELECT (single record)	view.php selects a member by member_id.
UPDATE	view.php updates the four editable member fields for the selected ID.
DELETE	view.php deletes the selected record by member_id.

Prepared statements: The code calls MySQLi `prepare()`, `bind_param()`, and `execute()` for INSERT, search, single-record SELECT, UPDATE, and DELETE. Placeholders keep user-supplied values separate from SQL syntax, helping prevent SQL injection and ensuring values are handled as data. The bind types used are strings for form fields and an integer for member IDs.

4. Testing, Deployment & Declaration

Test cases

These are suggested test cases based on the supplied implementation, not claims of completed execution. Record the actual result and attach screenshots from your browser/database before final submission.

#	Test input / action	Expected output
1	Open hosted index.php	Registration form and member directory load; count and rows display.
2	Submit all four valid fields	Record inserted; redirect to index.php?success=1 and success notice appears.
3	Submit with a required field empty	Submission rejected; error message asks to complete every field.
4	Enter text exceeding allowed length	Submission rejected with a length validation error.
5	Search a known name / club / interest	Matching rows display; result count updates.
6	Search a keyword with no match	"No matching members found" appears.
7	Open a member and save edited details	Record updates and directory shows updated data.
8	Delete a member and confirm	Record is deleted and directory shows deleted notice.
9	Open an invalid/nonexistent member ID	Redirects to directory with an error message.

Output screenshots to add

1. Registration page (form and directory).
2. Successful registration notice and newly listed record.
3. Search results.
4. Member details/edit form and update result.
5. phpMyAdmin table structure and records.

Deployment

Hosted URL: <http://clubmember.rf.gd/index.php?success=1>

Configuration note: The uploaded config.php still contains placeholder values for MySQL host, username, and password. Confirm that the deployed server configuration uses the actual InfinityFree credentials. Do not include database passwords in the report.

Declaration of Original Work

I hereby declare that the project titled "Club Registration System" has been developed by me as part of my academic work. The implementation and report are submitted for educational purposes. Any external resources used have been acknowledged where applicable.
